

House Price Prediction Project Summary

In this project, I built a machine learning model to predict house prices using different property features. I first cleaned the dataset, checked for missing values, and converted categorical data into a numerical format. After preparing the data, I trained two models: Linear Regression and Random Forest Regression.

The analysis showed that factors such as house area, number of bathrooms, air conditioning, and location have a strong impact on house prices. Among the two models, Random Forest performed better and provided more accurate predictions. The model was able to explain around 65% of the variation in house prices, which shows a reasonably good performance.

One interesting observation was that some additional facilities and amenities increased house prices even when the house size was similar. Based on these findings, real estate businesses can use such models to estimate property prices more accurately and understand which features add the most value to a property.
